Some 35 years ago I was somewhat precariously balanced in a drilling derrick aligning a whipstock into a directional hole in North Holland by the Stokenbury method, and no doubt thinking to myself that I was at the very forefront of technology. During the intervening period it has become obvious to many of us that some of the most significant technical advances in the oil business have been made in drilling, and particularly in the fields of offshore and directional drilling. It has also become apparent that the quality of the technical literature describing these advances has not kept pace with that of the advances themselves in many instances. A particular glaring example of this has been in the field of directional drilling where a large literature gap has existed for many years. I am delighted to see this gap now filled with the present volume by my friend Tom Inglis. Indeed it is only after reading his comprehensive book that I realise the extent of my own ignorance of the latest techniques of directional drilling and how desirable it was to have an authoritative text on the subject. I feel sure that this volume will be welcomed by the industry

and warmly recommend it to all who are in any way involved and interested in the fascinating world of drilling.

Horizontal Directional Drilling (HDD) is a growing and expanding trenchless method utilized to install pipelines from 2 to 60 inch diameters for lengths over 10,000 foot. To date, there are not many public documents where direct costs and bid prices incurred by HDD installations are available and analyzed. The objective is to provide a better understanding of the factors affecting the bid prices of these

projects. The first section of the thesis analyzes how project parameters such as product diameter, bore length and soil conditions affect the bid price of water and wastewater pipeline installations using HDD. Through multiple linear regressions, the effect of project parameters on bid prices of small, medium and large rigs projects is extracted. The results were further investigated to gain a better understanding of bid factors that influence the relationship between total cost and the project parameters. The second section uses unit cost, based on bid prices, to compare the costs incurred by defined categories. Parameters such as community type, product type, soil conditions, and geographical region were used in the analysis. Furthermore, using average unit cost from 2001 to 2009, HDD project cost trends are briefly analyzed against the main variations of the US economy from the same time horizon by using economic indicators. It was determined that project geometric factors influence more the bid price of small rig projects than large rig projects because external factors including market rates and economic situation have an increasing impact on bid prices when rig size increases. It was observed that bid price variation of HDD projects over years followed the same trend as the US economic variation described by economic indicators.

Horizontal Directional Drilling (HDD) : Utility and Pipeline Applications

Utility and Pipeline Applications

Horizontal directional drilling (HDD) is a versatile form of utility construction and has seen enormous growth in the last decade as it offers a clear alternative to conventional methods. Drilling is conducted in both the vertical and horizontal direction and can be steered

within limits, dependent upon subsurface conditions. HDD can install utilities from 1" to 48" in diameter and up to 6000 feet in length. The major utilities (gas, electric, telecommunications and water/sewer) can be installed with this technology. The construction process (pilot hole, reaming and pullback) along with the major components (drill rig, drill pipe, slurry, slurry recycling, survey equipment, drill bits, reamers and pipeline materials) will be discussed. The advantages of cost reduction, and environmental, social and time benefits will be examined in the context of numerous case studies. The challenges of proper soils information, subsurface conditions, training and knowledge, drilling fluids and binding of the drill pipe and reamer/bit will be discussed. Through constant innovation, HDD should remain state of the art for some time, and should be a consideration for the construction of any new utility within the size parameters.

Abstract: Abstract The Project has studied the use of horizontal directional coring (HDC) technique for ground investigation (GI) of tunnelling projects in Hong Kong. The aim is to explore the usefulness of HDC for Hong Kong tunnelling projects in future. The study of this new GI technique for tunnelling projects has covered the following three main considerations: - i. Technically feasible, ii. Economically viable, and iii. Programme acceptable. It was found that the advance in drilling technology and equipment has increased the efficiency which reduces both the cost per meter of HDC drilling as well as the drilling time. And make the HDC technique more practical in application for GI works. Calculations based on the Junk Bay Tunnel project suggest that the drilling cost of the HDC technique per meter is about 2 times the drilling cost of the traditional GI technique, but the cost per meter of relevant geological information is 2.4 times cheaper. In fact, this project is favourable to the traditional GI technique because of the thin overburden. For tunnel projects with

greater overburden thickness, the HDC technique will be more cost-effective. Not only can a HDC hole running along the tunnel alignment enable the precise ground conditions to be examined, but it also can identify any permeable zones with high water flux prior to tunnel excavation. Thus the impact to the surrounding environment due to ground water drawdown during construction stage can be better assessed at the design stage. - 4 - DOI:

Horizontal Directional Drilling (HDD) is a growing method for installation of pipes in urban areas and where trenching is impossible or undesirable; such as in crossing rivers, lakes, railways, and

special areas such as airports. This technique utilizes downhole cutting heads to create a pilot borehole before it is enlarged with back reamers to allow pulling back of a product pipe. The utilization of HDD for the installation of underground infrastructure (i.e., water, wastewater, oil and gas pipes, telecommunication, and power conduits), has shown a rapid growth compared to other trenchless technologies. HDD can install a range of pipe diameters from 2 to 60 inches utilizing different pipe materials including steel, high density polyethylene (HDPE), polyvinyl chloride (PVC), and ductile iron pipe (DIP) with minimum surface and daily life disruptions. Estimation of HDD productivity, project duration, and quantity of materials required, is a difficult task due to variable productivity conditions such soil, project, contractor, and machine conditions involved in operation. The objectives of this research are to define the significant subconditions that affect HDD productivity by utilizing the analysis of variance (ANOVA) model, to develop HDD productivity prediction model, and to develop HDD user interface as a planning tool for operation. Initially the main productivity conditions and subconditions were identified through literature review and consulting the HDD experts and professionals. A HDD questionnaire was designed, reviewed, and sent to HDD experts (contractors, design engineers, and consultants) to collect data addressing HDD operation conditions required for testing significance of subconditions and modeling operation productivity. HDD subconditions that show significance by ANOVA model analysis will be used to model HDD productivity in clayey and

rocky conditions. This model is applicable in predicting HDD productivity to estimate duration of HDD project, in addition to other project parameters such as quantities of materials required and cost of labor. Applications on HDD productivity model will be useful for consultants and contractors for planning, scheduling, and bidding of HDD projects during preconstruction stage, as well as during installation and construction.

Risks, Rewards and Regulation of Unconventional Gas

In the past decade, the field of trenchless technology has expanded rapidly in products, equipment, and utilization. This expansion would not have occurred without a strong increase in economic incentives to the user. Because the operating environment has changed, trenchless technology is often the preferred alternative to traditional methods of digging holes and installing conduits. The infrastructure in which we live has become more congested and has to be shared by several users. In addition, the cost of restoring a road or landscaped area after construction may be higher than the cost of installing the conduit. These factors add to the need for trenchless technology—the ability to dig holes without disturbing the surface. In some ways, trenchless technology is a futuristic concept. Ruth Krauss in a children's book of definitions wrote, "A Hole...Is to Dig." But this statement is not necessarily true. Today, a hole could be to bore. Trenchless technology is not new. But it certainly has become the buzzword of the construction industry and it appears that it will have a growing impact in the way contractors, utilities, and others install new facilities. Methods to bore horizontal holes were practiced as early as the 1800s, but this technology has

greatly changed. Today's tools include sophisticated drilling methods, state-of-the-art power systems, and electronic guidance techniques. These tools can bore faster, safer, and more accurately, and in many instances more economically, than open-clit methods. Technology has played an important role in these advances, but economics has become the driving force in making these systems popular.
