Thus the solution is $u = f(y - ax)$, with f an arbitrary function of one variable. This is exactly the same answer as before! Example 1. Partial Differential Equations: An Introduction with ... formula for the initial-value problem, due to d'Alembert in 1746. Assuming ϕ to have a continuous second derivative (written $\phi \in C^2$) and ψ to have a continuous first derivative ($\psi \in C^1$), we see from (8) that itself has continuous second partial derivatives in x and t . Partial Differential Equations: An Introduction, 2nd Edition We will find eigenvalues and eigenfunctions by separation of variables $u(r, \theta) = v(r)q(\theta)$, where $v(R) = 0$ and $q(\theta)$ is periodic with period 2π since $u(r, \theta)$ is single valued. This leads to $-1/r \mu(rv)'' + 1/r v q'' = \lambda v q$. Dividing by vq , provided $vq \neq 0$, we obtain $-1/r \mu(rv)'' + 1/r v q'' = \lambda v q$. Partial Differential Equations Thus the solution of the partial

differential equation is $u(x, y) = f(y + \cos x)$. To verify the solution, we use the chain rule and get $u_x = -\sin x f'(y + \cos x)$ and $u_y = f'(y + \cos x)$. Thus $u_x + \sin x u_y = 0$, as desired. Students Solutions Manual PARTIAL DIFFERENTIAL EQUATIONS The partial differential equation takes the form.

interval $[x - ct; x + ct]$ will be zero, while by periodicity, we can bring the interval $[x; x + ct]$ into the interval $(0; l)$ by subtracting one period $2l$. Thus, the solution can be written as $u(x; t) = \frac{1}{2} [f(x + ct) + f(x - ct)] + \frac{1}{2c} \int_{x-ct}^{x+ct} g(\xi) d\xi$.
